# **Optimisation Methods for Complex Event Recognition**

Periklis Mantenoglou

National & Kapodistrian University of Athens NCSR "Demokritos"

#### **Problem Statement & Motivation**

**Expressive Power: Cyclic Dependencies & Deadlines** 

Real-world **Complex Event Recognition** (CER) applications require **Stream Reasoning** (SR) techniques, which feature:

- highly-efficient reasoning over data streams
- high expressive power in spatiotemporal specifications
- robustness to uncertainty

The lack of a CER system which handles effectively all the above requirements motivates this thesis.

#### **Goal of the Thesis**

The Run-Time Event Calculus has been extended to express:

- cyclic dependencies in temporal specifications
- properties subject to deadlines

Efficient reasoning over specifications with cyclic dependencies or properties with deadlines requires:

- modelling specifications as locally stratified logic programs
- an incremental caching algorithm to avoid re-computations

The development of a logic-based Stream Reasoning system with the following properties:

- high efficiency and optimisation techniques
- high expressive power
- highly-efficient probabilistic inference algorithms
- neural-symbolic techniques

#### **Event Calculus**

- A **logic-based, temporal formalism** for representing and reasoning about events and their effects.
- built-in representation of the common-sense law of inertia
- succinct and intuitive definitions of domain specifications
- Iogic programming implementation

Figure 2. An example of modelling non-extensible (left) and extensible (right) deadlines in the Run-Time Event Calculus

#### **Online Reasoning under Uncertainty with the Event Calculus**

An online version of the Probabilistic Interval-based Event Calculus.

- online interval computation over temporal windows
- a **minimal memory** for storing potential starting points of future intervals
- a **bounded memory version** which further decreases memory requirements while maintaining high accuracy

#### **Run-Time Event Calculus**

- An Event Calculus dialect optimised for Stream Reasoning.
- Prolog implementation
- formal semantics
- windowing, caching and indexing techniques
- efficient enough for CER applications

#### **Probabilistic Event Calculus**

A probabilistic Event Calculus dialect for handling noise in the input data.

- built on top of ProbLog
- caching mechanism to avoid re-computations
- high accuracy in case of:
  - multiple complex event definitions
  - few probabilistic conjuncts in definitions
- probability fluctuations may deteriorate recognition

#### **Probabilistic Interval-based Event Calculus**

A batch processing algorithm over instantaneous recognition.

- succinct interval-based recognition
- robust to abrupt probability fluctuations
- Inear-time batch processing

#### Work So Far

We have worked on the following topics:

- Probabilistic Interval-based Event Calculus for online reasoning
- Run-Time Event Calculus with extended expressive power

 $\begin{array}{c} \mathsf{holdsAt}(F=V,T) \leftarrow \\ \mathsf{initiatedAt}(F=V,T_s), T_s < T, \\ \mathsf{not \ broken}(F=V,T_s,T). \\ \vdots \end{array} \\ \begin{array}{c} \mathsf{OPIEC} = \\ \mathsf{PIEC} + \\ \mathsf{support \ set} \end{array} \\ \begin{array}{c} \mathsf{OPIEC} = \\ \mathsf{PIEC} + \\ \mathsf{support \ set} \end{array} \\ \begin{array}{c} \mathsf{O.61} :: \ \mathsf{holdsFor}(moving(id_0,id_1),(T_1,T_2)) \\ \mathsf{O.88} :: \ \mathsf{holdsFor}(moving(id_0,id_5),(T_3,T_6)) \\ \mathsf{O.66} :: \ \mathsf{holdsFor}(moving(id_0,id_5),(T_6,T_7)) \\ \mathsf{O.89} :: \ \mathsf{holdsFor}(moving(id_0,id_1),(T_8,T_{12})) \\ \mathsf{O.67} :: \ \mathsf{holdsFor}(meeting(id_1,id_5),(T_{14},T_{18})) \\ \vdots \end{array} \\ \end{array} \\ \end{array}$

### **Further Work**

In the future, we aim to:

- develop highly-efficient probabilistic inference algorithms for Event Calculus theories
- Integrate probabilistic reasoning in the Run-Time Event Calculus
- Combine these approaches in a neuro-symbolic framework
